

FEATURES

LO/RF Frequency:	11 – 14 GHz
I/Q Bandwidth:	275 MHz
Input IP3:	+20 dBm
Input P1dB:	+12 dBm
Amplitude Imbalance:	±0.2 dB
Phase Error:	±2 Degrees
LO Power:	+5 dBm
DC Supplies:	+5V @ 110 mA, -5V @ 40 mA

DESCRIPTION

When a LO signal is applied, the AD110140B converts the RF input signal centered at the LO frequency directly to baseband I and Q outputs. Integral low pass filters provide I and Q anti-alias filtering. The AD110140B's differential I and Q outputs can be directly connected to 50 Ω digitizers or instrumentation.

The AD110140B can be easily interfaced with differential high-speed analog-to-digital converters (ADCs). For more information, please refer to the **APPLICATIONS** section of this datasheet.

TYPICAL APPLICATION: DIRECT CONVERSION RECEIVER

ELECTRICAL SPECIFICATIONS

Test Conditions: +25°C, LO = +5 dBm, RF input = +0 dBm @ LO+100 kHz unless otherwise noted.

PARAMETER	TEST CONDITIONS	MIN	TYP	MAX	UNITS
LO/RF Frequency Range ¹		11.0		14.0	GHz
+5V DC Supply Range		+4.9	+5.0	+5.2	V
-5V DC Supply Range		-5.2	-5.0	-4.9	V
+5V DC Supply Current			110		mA
-5V DC Supply Current			40		mA
LO Power		+3	+5	+7	dBm
LO VSWR			1.5:1		Ratio
RF VSWR			2.5:1		Ratio
I/Q Baseband Filter Bandwidth ²	<1 dB Flatness	DC		275	MHz
I/Q Baseband Filter Stop Band ²	>25 dB Rejection	450		7000	MHz
I/Q Differential Output Impedance			100		Ω
I/Q DC Offset		-8	-4	+8	mV
Conversion Loss			9	11	dB
Noise Figure			9.5		dB
Input IP3	2-Tone, Δf = 1 MHz		+20		dBm
Input P1dB			+12		dBm
LO-RF Isolation	No RF input drive		45		dB
LO-I/Q Isolation	No RF input drive		60		dB
Amplitude Imbalance		-0.6	±0.2	+0.6	dB
Quadrature Phase Error		-5.0	±2	+3.0	Degree
Operating Temperature Range		-40		+85	°C
LO/RF Input Power w/o Damage				+15	dBm

Notes:

1. When RF > LO frequency: I = cos(), Q = sin()
2. Standard low pass filters. Contact factory for other options.

APPLICATIONS

LO Input Drive Requirements

The AD110140B requires an LO signal be applied at +5 dBm nominal to demodulate the RF input. If the LO is pulsed, the I and Q outputs will be valid approximately 15 ns after the LO pulse is applied.

Interfacing with Differential ADCs

The AD110140B's differential I and Q outputs can be interfaced with differential high-speed analog-to-digital converters (ADCs). The AD110140B's I and Q outputs are DC-coupled with a common-mode voltage of 0 V (ground). Most ADCs have a positive input common-mode voltage requirement between 0.8 V and 2.5 V.

Series DC blocking capacitors can be used to float the I and Q signals to the ADC's common-mode voltage. Figure 1 shows the AD110140B interfaced to a dual ADC with differential inputs.

Figure 1. Differential ADC Interface

I/Q DEMODULATION

The AD110140B converts an RF signal centered at the LO frequency into I and Q baseband outputs. To understand the process of I/Q demodulation, first consider the case of an ideal demodulator. The original RF signal is defined using the complex envelope representation:

$$z(t) = \mathbf{R}[A(t)e^{j(2\pi f_c t + \phi(t))}] \quad (1)$$

$z(t)$ is the real time-domain signal present at the RF port of the demodulator centered at frequency f_c . $z(t)$ has amplitude $A(t)$ in volts and phase $\phi(t)$ in radians. Both $A(t)$ and $\phi(t)$ are time-dependent. $\mathbf{R}[\]$ denotes taking only the real part of the expression.

$z(t)$ can be written in terms of two orthogonal signals, $I(t)$ and $Q(t)$:

$$z(t) = I(t) \cos(2\pi f_c t) - Q(t) \sin(2\pi f_c t) \quad (2)$$

where

$$A(t) = \sqrt{I^2(t) + Q^2(t)} \quad (3)$$

and

$$\phi(t) = \arctan(Q(t), I(t)) \quad (4)$$

An ideal quadrature demodulator extracts the $I(t)$ and $Q(t)$ signals defined in (2). A real demodulator introduces several linear distortions including conversion loss, amplitude imbalance, quadrature phase error, I-axis phase rotation, and I/Q DC offsets. After applying these linear distortions, the real measured I and Q output signals are obtained:

$$\hat{I}(t) = C_I (\cos \theta_R I(t) - \sin \theta_R Q(t)) + B_I \quad (5)$$

$$\hat{Q}(t) = C_Q (\cos \theta_R \cos \theta_E Q(t) - \sin \theta_E I(t) + \sin \theta_R I(t)) + B_Q \quad (6)$$

C_I is the I channel conversion loss factor, C_Q is the Q channel conversion loss factor, θ_R is the I-axis phase rotation in radians, B_I is the I channel DC offset in volts, B_Q is the Q channel DC offset in volts, and θ_E is the quadrature phase error in radians.

When the LO and RF frequencies are not equal, θ_R can be set to 0 to simplify (5) and (6):

$$\hat{I}(t) = C_I I(t) + B_I \quad (7)$$

$$\hat{Q}(t) = C_Q (\cos \theta_E Q(t) - \sin \theta_E I(t)) + B_Q \quad (8)$$

θ_R is only important in applications when the phase difference between the RF and LO signals must be known (i.e. phase detector).

Example: Apply a 12 GHz CW LO signal at +5 dBm and a 12.001 GHz CW RF signal at -2 dBm. To estimate the AD110140B's $\hat{I}(t)$ and $\hat{Q}(t)$ signals, start by determining all the parameters in (7) and (8).

C_I and C_Q are determined by the conversion loss and amplitude imbalance of the AD110140B. From the datasheet's typical performance plots at 12 GHz, use 8.8 dB conversion loss and -0.21 dB amplitude imbalance to find C_I and C_Q :

$$\frac{C_I + C_Q}{2} = 10^{(-8.8/20)} = 0.3631 \quad (9)$$

$$20 \log\left(\frac{C_Q}{C_I}\right) = -0.21 \quad (10)$$

$$C_I = 0.3675 \quad C_Q = 0.3587 \quad (11), (12)$$

Quadrature phase error and DC offsets are also obtained from the typical performance plots at 12 GHz:

$$\theta_E = -1.5 \text{ Deg.} = -0.026 \text{ Radians} \quad (13)$$

$$B_I = -0.005V \quad B_Q = -0.004V \quad (14), (15)$$

The next step in estimating $\hat{I}(t)$ and $\hat{Q}(t)$ is to calculate the ideal $I(t)$ and $Q(t)$ from the RF input signal. Given that the RF signal frequency is 1 kHz greater than the LO frequency, $I(t)$ and $Q(t)$ define an upper sideband tone of 1 kHz having a constant amplitude of:

$$\frac{A^2}{0.1} = 10^{(-2.0/10)} \quad (16)$$

$$A = 0.2512V \quad (17)$$

From (3) and (17) we know:

$$I(t) = 0.1776 \cos(2\pi 1000t) \quad (18)$$

and

$$Q(t) = 0.1776 \sin(2\pi 1000t) \quad (19)$$

The final step in estimating $\hat{I}(t)$ and $\hat{Q}(t)$, the demodulator's real I and Q outputs signals, is to insert (11), (12), (13), (14), (15), (18), and (19) into (7) and (8) giving the final result:

$$\hat{I}(t) = 0.065 \cos(2\pi 1000t) - 0.005$$

$$\hat{Q}(t) = 0.064 \sin(2\pi 1000t - 0.026) - 0.004$$
